2.1 Background

Zones extend the isolation of processes beyond what is traditionally provided by UNIX and UNIX-like systems, including OpenBSD. Traditionally, all processes running on an OpenBSD are visible to all other processes. This can be demonstrated by running commands like top(1), ps(1), and pgrep(1)/pkill(1), which can show all processes running in a system:

While all processes are visible to each other, they are restricted from interacting with each other based on the user that each process is running as. A non-root user can only signal their own processes. Attempts to signal processes running as another user fails:

n-global) zones, and

ever, non-root users

running as the same

utilities and adds a

sub-commands that

e name specified by

However, the root user is allowed to signal any process:

3 Zones Implementation

- ⁴³ Zones are implemented for this assignment to add further isolation of processes. Processes
- running within a zone can only see and interact with processes running within the same zone,
- regardless of which user within the zone is running the commands. This implementation is
- loosely modelled on the design of Solaris Zones as described in PSARC/2002/174.
- The exception to this enhanced isolation is for processes running in the "global" zone, which is
- 48 the default zone that is created and exists on boot. Processes running in the global zone can
- 49 see all other processes
- 50 the root user in the glo
- in the global zone cann
- 52 11Ser
- The provided diff imple
- 54 zone(8) command and
- 55 expose the functionality

57 zone_create()

```
zoneid_t zone_cr
```

- 58 zone_create() creates
- 59 zonename.
- 50 zone_destroy()

int zone_destro, zonera_o z,

- zone_destroy() deletes the specified zone instance. The zone must have no running processes
 inside it for the request to succeed.
- 63 zone_enter()

```
int zone_enter(zoneid_t z);
```

200 zone enter() moves the current process into the specified zone.

65 zone list()

```
int zone_list(zoneid_t *zs, size_t *nzs);
```

In the global zone zone_list() provides the list of zones in the running system as an array of

zoneid_ts. If run in a non-global zone, the list will only contain the current zone.

68 zone_name()

```
int zone_name(zoneid_t z, char *name, size_t namelen);
```

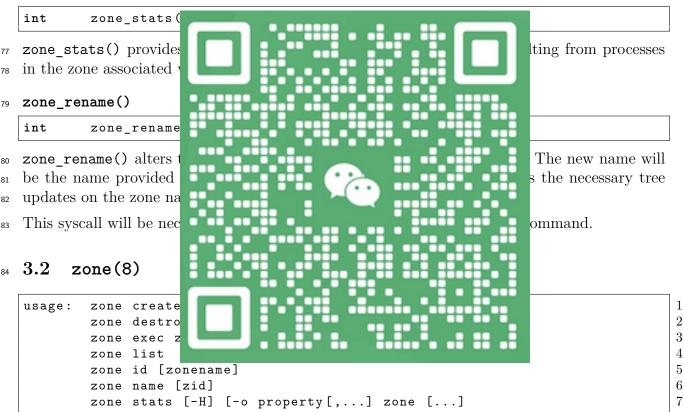

The zone_name() syscall provides the name of the zone identified by the z argument. If run in a non-global zone the z id must be the identifier for the current zone. In the global zone it can be any zone identifier.

72 zone_id()

```
zoneid_t zone_id(const char *name);
```

zone_id() provides the id associated with the name zone. If run in a non-global zone, only the current zone name may be specified. If name is a NULL pointer the zone id calling process is running in is returned.

76 zone_stats()

The zone(8) program uses the zone syscalls to allow systems administrators or operators to use the zone subsystem in the kernel.

87 zone create

zone create uses the zone create() syscall to create a zone with the specified name.

89 zone destroy

zone destroy uses the zone_destroy() syscall to create a zone with the specified name. If a zone with the specified name does not exist, zone(8) will attempt to interpret the argument as a numeric zone identifier.

zone exec

zone exec uses the zone_enter() syscall to move itself into the specified zone, and then executes the program. If a zone with the specified name does not exist, zone(8) will attempt to interpret the argument as a numeric zone identifier.

zone list

zone list uses the zone list() syscall to fetch a list of ids for the currently running zones, and iterates over it calling the zone name() syscall to print out the list of zone ids and names.

zone name / zone id 100

zone name and zone id use their associated syscalls zone name() and zone id() to return 101 the name of a zone given its id, or the id of a zone given its name. 102

zone stats 103

zone stats uses the zone_stat() syscall to obtain and print out to the user a series of statis-104 tics from processes running in the manual page in zone(8) for more information. 106

3.3 Your Tasks

107 You will be adding add mands, adding three 108 new zone(8) sub-com to the kernel zones 109 system to support then 110 an associated "user" Your additional function 111 and "group", and this file. Your task is to associate zones with a the zone and users who are in that group hether they are the 114 owner of the zone). 115 In short, where zones a allow the owner of 116 a zone and a different g 117 The additional sub-com e, which will change 118 the name of a zone; zo in a manner similar 119 to the existing chown (8 a zone in a manner 120

Instructions 4

```

As you add the functionality specified in the next sections, some of these steps will be repeated.
eg, changing the kernel means rebuilding and installing the kernel. Adding a syscall means
making the syscall stub as a function visible in the headers (make includes), and callable
through libc.

A note on errors

We have over-specified the errors you should return from your syscalls - if you do not require an error code (for example, never returning ENOMEM on memory failures because you never allocate any memory) then you do not have to use it. The reverse is also true - if you find an error case that is not listed, choose an appropriate error from errno(2). We will not explicitly test all errors, but during your code interview, we will expect you to be able to explain the suitability of the error codes you use.

36 4.2 Zone Rename

The zone(8) commands should be extended to enable renaming of zones. Zones should only be able to be renamed by the owner, root, or members of the zone's group. Additionally, the global zone cannot be renamed, and zone names must be unique.

4.3 Modifications to Existing Syscalls

zone_create() syscall

140

141

The zone_create() syscall should now ensure that the created zone is associated with the group of the user that created it, as well as the user themself. Additionally, this will mean ensuring that non-root users can create zones. The definition of zone_create() should not change - it should still take a single char *zonename as its argument.

146 All other syscalls

The full suite of zone_* syscalls should permit users with matching credentials (owner or group)
to perform zone operations on them, not only the root user. The credentials may be changed
so appropriate synchronisation should be used. Namely, we expect that, unless credentials are
being changed by another thread, authorisation should be non-blocking.

4.4 Zone name and zone list

zone_name() syscall

order of the additional

The zone_name() syscall should be renamed to zone_info(). Subsequently, it should return not only the name and namelen, but also the zone, user and group id, preferably all bundled in a struct format. However you may pass back one or more of these as individual parameters if that is easier. The zone(8) userland sub-command for zone name should also be modified in line with these changes - the name should be changed to zone info and the additional information should be provided to the user. Alternatively, you may also create zone info as an independent command.

zone list

The zone list subcommand should now take flags: -o and -g. If the -o flag is provided, the owner of the zone should be printed, and if the -g flag is provided, the zone's group should be printed. If both flags are provided, print both. The extra fields should be printed as extra columns in the current table format. zone id and name must be displayed first. However, the

The two subcommands the name of a zone and the zone and the name of a zone and the name of a zone and the name of a zone and the zone

the specified name. If a zone with the name zonename does not exist, zone (8) will attempt to interpret the argument as a numeric zone identifier.

zone chgrp behaves similarly, but instead, it uses the zone_chgrp() syscall to change the zone's group to the specified group name.

To support these subcommands, you will need to implement the following system calls:

zone_chown() syscall

```
int zone_chown(zoneid_t z, uid_t user);
```

The zone_chown() syscall alters the owner of the zone identified by the z argument. The new owner should be the owner identified by the user argument. If called from a non-global zone, then the z id must be the identifier for the current zone, but in the global zone, it can be any zone identifier. This means that to the user, a non-global zone should only be able to see itself.

- ENOMEM the system was not able to allocate memory
- EINVAL the zone to alter was the global zone

zone_chgrp() syscall 188

```
int
        zone_chgrp(zoneid_t z, gid_t group);
```

The zone chgrp() syscall alters the owner of the zone identified by the z argument. The new owner should be the group identified by the group argument. If called from a non-global zone, then the z id must be the identifier for the current zone, but in the global zone, it can be any zone identifier. This means that to the user, a non-global zone should only be able to see itself.

Potential Errors:

193 • EPERM - the use 194 ESRCH - the zon 195 ENOMEM - the 196 EINVAL - the zo 197 5 Other Req 198 5.1Code Style Your code is to be writt style(9) man page. 200 An automatic tool for 201 https://stluc.manta 202 This tool will be used t 203 5.2Compilation 204

Your code for this assignment is to be built on an amd64 OpenBSD 7.5 system identical to your 205 course-provided VM. 206

The following steps must succeed: 208

- make obj; make config; make in src/sys/arch/amd64/compile/GENERIC.MP
- make obj; make includes in src
- make obj; make; make install in src/lib/libc
- make obj; make; make install in src/usr.sbin/zone

The existing Makefiles in the provided code are functional as-is, but may need modification 213 as part of your work for this assignment. Note that the existing Makefile ensures the -Wall 214 flag is passed to the compiler, as well as a few other warning and error-related flags. 215

5.3 Provided code

216

236

239

240

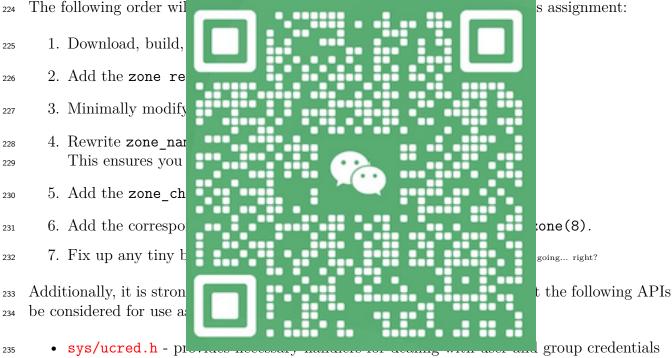

The provided code, which forms the basis for this assignment, can be downloaded as a single patch file at:

https://stluc.manta.uqcloud.net/comp3301/public/2024/a1-zones-base.patch

You should create a new a1 branch in your repository based on the openbsd-7.5 tag using git checkout, and then apply this base patch using the git am command:

```
$ git checkout -b a1 openbsd-7.5
$ ftp https://stluc.manta.uqcloud.net/comp3301/public/2024/a1-zones-base.
    patch
$ git am < a1-zones-base.patch
$ git push origin a1</pre>
$ 1
2
```

5.4 Recommendations

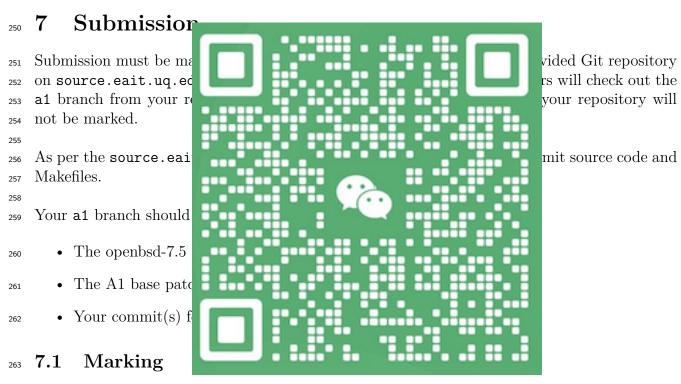

- copyin(9)/copyout(9) provides the ability to copy data across the userspace boundary
- user_from_uid(3) conversions from group/user name to id and back
- strtonum(3) BSD style safe string to int conversions
 - Finally, you may wish to look at the header file sys/proc.h to see how user and group credentials are currently stored by threads.

6 Reflection

246

- Provide a reflection on your implementation by briefly answering the following questions:
- 243 1. Describe the steps you took or draw a flowchart.
- 2. Describe an error that you encountered.
- 3. Describe how the error was debugged.
 - 4. Describe how the bug was solved.

Upload your answers as a pdf to the Blackboard a1 reflection submission. Page length is a maximum 2 pages or less. Pdf name must be your STUDENT_NUMBER_a1.pdf. Note this is your XXXXXXXX ID number and not sXXXXXXXX login.

Your submission will be marked by course tutors and staff, during an in-person demo with you, at your lab session during the due week. You must attend your session, in-person, otherwise your submission will not be marked. Online attendence, e.g. zoom, is not permitted.
